Operator Overloading

C++ Object Oriented Programming

Pei-yih Ting

NTOU CS

Contents

- ❖ Basics
- ❖ Consider all usages of the overloaded operator
- ❖ Complex number example
- ❖ Do not change semantics
- ❖ Overload related sets of operators
- ❖ Time example
- ❖ Prefix ++ and postfix ++
- ❖ operator[]
- ❖ Assignment operator: operator=
- ❖ Function call operator: operator()
- ❖ Smart pointers
- ❖ Memory allocation operators: operator new/delete
- ❖ Type conversion operators
- ❖ Unary operator+

Basic Overloading

❖ Operator overloading in ANSI C

```
int x, y, z;  
double q, r, t;  
z = x + y;  
q = r + t;
```

The same operator can do different things.

❖ Overloading in C++

```
Array();  
Array(int arraySize);
```

Overloaded constructors

```
void quit() {  
    cout << "So you want to save before quitting?\n";  
}  
void quit(char *customMessage) {  
    cout << customMessage << endl;  
}
```

Functions with the same name can do different jobs.

Operator Overloading

❖ There are two possibilities for the following

```
MyClass obj1, obj2;
```

```
obj1 + obj2;
```

Compiler would translate the above into one of the following function call if one of them is defined:

★ First: calling member function

```
MyClass MyClass::operator+(MyClass rhs)
```

i.e. **obj1.operator+(obj2)**

★ Second: calling global function

```
MyClass operator+(MyClass lhs, MyClass rhs)
```

i.e. **operator+(obj1, obj2)**

(If both of them are defined, the **global one will be invoked.**

Do not take this as a practicing rule!!)

Operator Overloading (cont'd)

- ✧ Consider the following MenuItem class which describes the item on a restaurant menu

```
class MenuItem {  
public:  
    MenuItem(int itemPrice, char *itemName);  
    MenuItem(const MenuItem &src);  
    ~MenuItem();  
    void display() const;  
private:  
    int m_price;  
    char *m_name;  
};
```

- ✧ We would like to do the following

```
void main() {  
    MenuItem item1(250, "Chicken Florentine");  
    MenuItem item2(120, "Tiramisu");  
    cout << "You ordered the following items:";  
    item1.display(); item2.display();  
    cout << "The total is $" << item1 + item2 << ".\n";  
}
```

First Solution with Overloading

- ❖ Add a member function which overloads `operator+()`

```
class MenuItem
{
public:
    MenuItem(int itemPrice, char *itemName);
    MenuItem(const MenuItem &src);
    ~MenuItem();
    void display() const;
    int operator+(const MenuItem &secondItem) const;
private:
    int m_price;
    char *m_name;
};
```

-----or MenuItem secondItem

- ❖ The function is defined as follows

```
int MenuItem::operator+(const MenuItem &secondItem) const
{
    return m_price + secondItem.m_price;
}
```

Left operand of +

Right operand of +

Behavior of Overloaded Operator

- ✧ Add a third menu item

```
MenuItem item1(250, "Chicken Florentine");  
MenuItem item2(120, "Tiramisu");  
MenuItem item3(50, "Mineral Water");  
int total;
```

```
total = item1 + item2 + item3;
```

error C2677: binary '+' : no global operator defined which takes type
'class MenuItem' (or there is no acceptable conversion)

Why?

- * **item1** + item2 returns an int
- * you then have **int** + MenuItem (item3)

The overloaded member function can only be called by an instance of the class.

- ✧ Solution: make the overloaded function toplevel

```
int operator+(int currentTotal, MenuItem &secondItem)  
{  
    return currentTotal + secondItem.m_price;  
}
```

make this function
a friend of MenuItem

could be reference or value

Behavior (cont'd)

- ❖ The following statement still fails

```
item1 + (item2 + item3)
```

```
error C2678: binary '+' : no operator defined which takes a left-hand  
operand of type 'class MenuItem' (or there is  
no acceptable conversion)
```

Why?

- ★ This is equivalent to `MenuItem(item1) + int`

- ❖ Solution: add another overloaded operator function

```
int MenuItem::operator+(int currentTotal) {  
    return currentTotal + m_price;  
}
```

Why does this function not have to be toplevel (i.e. global)?

- ❖ Conclusion

When you overload an operator, you are responsible for the correct behavior of the operator in **all** possible circumstances.

Alternative Solution

- Use **conversion constructor** together with global **operator+(const MenuItem &, const MenuItem &)**

```
class MenuItem {  
    friend int operator+(const MenuItem &firstItem,  
                        const MenuItem &secondItem);  
public:  
    MenuItem(int itemPrice, char *itemName);  
    MenuItem(int price);  
    MenuItem(const MenuItem &src);  
    ~MenuItem();  
    void display() const;  
private:  
    int m_price;  
    char *m_name;  
};
```

- The conversion constructor

```
MenuItem::MenuItem(int price): m_price(price), m_name(0) {  
}
```

- Overload the operator at the toplevel with two MenuItem objects

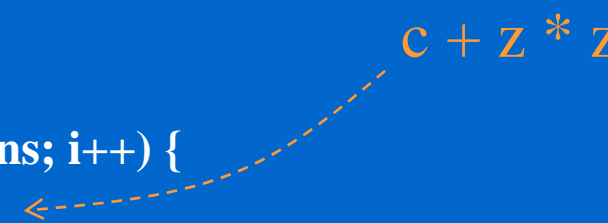

```
int operator+(const MenuItem &firstItem, const MenuItem &secondItem) {  
    return firstItem.m_price + secondItem.m_price;  
}
```

Complex Number Example

- ❖ Complex class represents a complex number (real, imaginary), define two mathematic operations (no side effect)

```
Complex Complex::add(const Complex &secondNumber) const {  
    Complex tmp(m_real+secondNumber.m_real,  
                m_imaginary+secondNumber.m_imaginary);  
    return tmp;  
}  
Complex Complex::multiply(const Complex &secondNumber) const {  
    Complex tmp(m_real*secondNumber.m_real-  
                m_imaginary*secondNumber.m_imaginary,  
                m_real*secondNumber.m_imaginary+  
                m_imaginary*secondNumber.m_real);  
    return tmp;  
}
```

- ❖ main()

```
Complex c(0.1, 0), z(0, 0);  
for (int i=1; i<MaxIterations; i++) {  
    z = c.add(z.multiply(z));   
    if (fabs(z.getRealPart())>2.0 || fabs(z.getImaginaryPart())>2.0) break;  
}
```

Complex Number (cont'd)

✧ Let us overload + and *

```
Complex Complex::operator+(const Complex &secondNumber) const {  
    Complex tmp(m_real+secondNumber.m_real,  
                m_imaginary+secondNumber.m_imaginary);  
    return tmp;  
}  
Complex Complex::operator*(const Complex &secondNumber) const {  
    Complex tmp(m_real*secondNumber.m_real-  
                m_imaginary*secondNumber.m_imaginary,  
                m_real*secondNumber.m_imaginary+  
                m_imaginary*secondNumber.m_real);  
    return tmp;  
}
```

✧ main()

```
Complex c(0.1, 0), z(0, 0);  
for (int i=1; i<MaxIterations; i++) {  
    z = c + z * z;  
    if (fabs(z.getRealPart())>2.0 || fabs(z.getImaginaryPart())>2.0) break;  
}
```

✧ Related operators +=, *=

Dubious Operator Overloading

- ❖ Here are some actual examples from a textbook
Can you guess what these operators mean?

```
Stack s;  
...  
s+5;  
x = s--;
```

They are used to stand for the following

```
s.push(5);  
x = s.pop();
```

- ❖ Overloading obscure operators can be dangerous

Redefine \wedge (bitwise XOR) to mean "power"

It won't work as expected, ex. Integer x;

```
x ^ 2 + 1 // if x is 5, you want to get 26, but you get 125 instead
```

Reason: \wedge has lower precedence than +

- ❖ Illegal overloading

```
int operator+(int number1, int number2) {  
    return number1-number2;  
}
```

error C2803: 'operator +' must have at least one formal parameter of class type

Operator Precedence & Association

1	::	Scope resolution	None
2	::	Global	None

59	=	Bitwise inclusive OR assignment	Right to left
60	^=	Bitwise exclusive OR assignment	Right to left
61	,	Comma	Left to right

Overload All Related Operators

- ❖ If you provide a + operator, you should also provide related operators such as += and ++
- ❖ Let us define a Time class that allows addition

```
class Time {  
public:  
    Time();  
    Time(int hours, int minutes, int seconds);  
    void display();  
    Time operator+(Time secondTime);  
private:  
    int m_hours;  
    int m_minutes;  
    int m_seconds;  
    void normalize();  
};  
Time::Time(): m_seconds(0), m_minutes(0), m_hours(0) {  
}  
Time::Time(int hours, int minutes, int seconds)  
    : m_hours(hours), m_minutes(minutes), m_seconds(seconds) {  
    normalize();  
}
```

Overload + and *

❖ operator+

```
Time Time::operator+(Time secondTime){
    int hours, minutes, seconds;
    hours = m_hours + secondTime.m_hours;
    minutes = m_minutes + secondTime.m_minutes;
    seconds = m_seconds + secondTime.m_seconds;
    return Time(hours, minutes, seconds);
}
```

Note; we do not call normalize() in this case

❖ operator*=

```
void Time::operator*=(int num) {
    m_hours *= num;
    m_minutes *= num;
    m_seconds *= num;
    normalize();
}
```

This operator does not return anything and has side effects.

```
Time time1(20, 15, 0);
Time time2(3, 45, 10);

Time time3 = time1 + time2;
time3.display();
cout << endl;

time2 *= 3;
time2.display();
cout << endl;
```

operator++

- ❖ ++ and -- come in **postfix** and **prefix** formats

```
int x, y;  
x = 5;  
y = x++;  
cout << "x is " << x << " and y is " << y << "\n";
```

Output
x is 6 and y is 5

```
x = 5;  
y = ++x;  
cout << "x is " << x << " and y is " << y << "\n";
```

Output
x is 6 and y is 6

- ❖ How does C++ know which ++ operator you want to override?

- ★ Postfix syntax

Time **Time::operator++(int)** // int argument is ignored

- ★ Prefix syntax

Time **&time::operator++()**

operator++ (cont'd)

❖ Postfix operator

```
Time Time::operator++(int) {  
    Time tmp = *this;  
    m_seconds++; normalize();  
    return tmp;  
}
```

❖ Usage

```
Time firstTime(1, 1, 3), secondTime;  
secondTime = firstTime++;  
firstTime.display(); secondTime.display();
```

```
Output  
01:01:04  
01:01:03
```

❖ Prefix operator

```
Time &Time::operator++() {  
    m_seconds++; normalize();  
    return *this;  
}
```

❖ Usage

```
Time firstTime(1, 1, 3), secondTime;  
secondTime = ++firstTime;  
firstTime.display(); secondTime.display();
```

```
Output  
01:01:04  
01:01:04
```

operator[]

- ❖ Example: An array class which includes bounds checking

```
class Array {
public:
    Array();
    Array(int arraySize);
    ~Array();
    void insert(int slot, int element);
    int get(int slot) const;
private:
    int m_arraySize;
    int *m_array;
};

void Array::insert(int slot, int element) {
    if (slot < m_arraySize && slot >= 0)
        m_array[slot] = element;
    else
        cout << "Subscript out of range\n";
}

int Array::get(int slot) const {
    if (slot < m_arraySize && slot >= 0)
        return m_array[slot];
    cout << "Subscript out of range\n";
    return 0;
}
```

```
Array data(5);
for (int i=0; i<5; i++)
    data.insert(i, i*2);
cout << data.get(3);
```

We prefer the following: the same syntax as accessing a "normal" array.

```
Array data(5);
for (int i=0; i<5; i++)
    data[i] = i*2;
cout << data[3];
```

operator[] (cont'd)

```
class Array {  
public:  
    Array();  
    Array(int arraySize);  
    ~Array();  
    int &operator[](int slot);  
private:  
    int m_arraySize;  
    int *m_array;  
};  
  
int &Array::operator[](int slot) {  
    if (slot < m_arraySize && slot >= 0)  
        return m_array[slot];  
    cout << "Subscript out of range\n";  
    return m_array[0];  
}
```

l-value is an object that persists beyond a simple expression
r-value is a **temporary** value that does not persist beyond the expression that uses it

works as an l-value

The Account Example

```
class Account
{
public:
    Account(const char *name, const char *phone, const char *address);
    ~Account();
    ...
private:
    char *m_name;
    char *m_phone;
    char *m_address;
};

Account::Account(const char *name, const char *phone, const char *address)
{
    m_name = new char[strlen(name)+1]; strcpy(m_name, name);
    m_phone = new char[strlen(phone)+1]; strcpy(m_phone, phone);
    m_address = new char[strlen(address)+1]; strcpy(m_address, address);
}

Account::~Account()
{
    delete[] m_name; delete[] m_phone; delete[] m_address;
}
```

Assignment Operator

- ❖ Where is the assignment operator invoked?

```
Account customer1("abc", "1234", "ABC street");  
Account customer2, customer3; // assume default ctor defined  
customer2 = customer1;  
customer2.operator=(customer1);  
customer3 = customer2 = customer1;
```

- ❖ Note: `Account customer2 = customer1;`
does NOT invoke the assignment operator

- ❖ What is its prototype?

```
Account &operator=(Account &rhs);
```

No extra copy ctor invoked

Designed for continuous assignment statements

```
customer3.operator=(customer2.operator=(customer1));
```

Assignment Operator (cont'd)

- ✧ Again, if the class being designed allocates its own resources. It is quite often to see the dtor, copy ctor, and the assignment operator occurring together.
- ✧ There are **seven** important things to do in an assignment operator

```
Account &Account operator=(Account &rhs)
{
  ① if (&rhs == this) return *this; ← Detecting self assignments
  ② delete[] m_name; delete[] m_phone; delete[] m_address;
  ③ { m_name = new char[strlen(rhs.m_name)+1];
    m_phone = new char[strlen(rhs.m_phone)+1];
    m_address = new char[strlen(rhs.m_address)+1];
  ④ { strcpy(m_name, rhs.m_name);
    strcpy(m_phone, rhs.m_phone);
    strcpy(m_address, rhs.m_address);
  ⑤ // invoke the base class assignment operator
  ⑥ // invoke the component object assignment operator
  ⑦ return *this;
}
```

Related Operators of Assignment

- ❖ If you overload assignment, you might like to overload equality

```
bool Account::operator==(const Account &rhs) const {  
    if ((strcmp(m_name, rhs.m_name)==0) &&  
        (strcmp(m_phone, rhs.m_phone)==0) &&  
        (strcmp(m_address, rhs.m_address)==0))  
        return true;  
    else  
        return false;  
}
```

- ❖ Usage

```
Account customer1("abc", "1234", "ABC street"), customer2;  
customer2 = customer1;  
...  
if (customer2 == customer1) ...
```

- ❖ Other related operators

- * `bool operator!=(const Account &rhs) const;`
- * `bool operator<(const Account &rhs) const;`
- * `bool operator<=(const Account &rhs) const;`
- * `bool operator>(const Account &rhs) const;`
- * `bool operator>=(const Account &rhs) const;`

Function Call operator()

- ❖ Overload operator() to make an **object** that stands for a function **behave like a function**

often called a **Functor**

```
class Polynomial {
public:
    Polynomial(double secondOrder, double firstOrder, double constant);
    double operator()(double x);
private:
    double m_coefficients[3];
};
Polynomial::Polynomial(double secondOrder, double firstOrder, double constant) {
    m_coefficients[2] = secondOrder;
    m_coefficients[1] = firstOrder;
    m_coefficients[0] = constant;
}
double Polynomial::operator()(double x) {
    return m_coefficients[2]*x*x + m_coefficients[1]*x + m_coefficients[0];
}
void main() {
    Polynomial f(2, 3, 4);
    int x = 2;
    cout << f(x);
}
```

Output
18

Other Uses of operator()

- ❖ operator() is the only operator that can take **any number of arguments**
- ❖ Imagine you had a matrix class (two-dimensional array): You would like to avoid accessor and mutator functions. One idea is to overload the operator[], the subscript operator.

- ❖ This is **illegal**, no such [][] operator

```
int &operator[][](int x);
```

- ❖ The closest equivalent to array subscripting is to overload operator() with two arguments

```
int &Matrix::operator()(int x, int y) {  
    if (x >= 0 && x < m_dim1 && y >= 0 && y < m_dim2)  
        return m_matrix[x][y];  
    cout << "out of bounds!\n";  
    return m_matrix[0][0];  
}
```

- ❖ Usage

```
Matrix matrix(5,10);  
matrix(2,3) = 10;   cout << matrix(2,3);
```

Smart Pointers

- ❖ When you overload `->`, you get a *smart pointer*
The primary purpose of a smart pointer is to **link a member function of a subobject to the main object**

- ❖ Example:

```
class Person {  
public:  
    Person(char *name, int age)  
    int getAge();  
    Name *operator->();  
private:  
    Name *m_ptrNameObject; // must be a pointer  
    int m_age;  
};  
class Name {  
public:  
    Name(char *name);  
    ~Name();  
    const char *getName();  
private:  
    char *m_name;  
};
```

- ★ The goal is to link `Name::getName()` to an instance of class `Person`

Smart Pointers (cont'd)

- ❖ The overloaded function

```
Name *Person::operator->() {  
    return m_ptrNameObject;  
}
```

- ❖ Using the smart pointer

```
void main() {  
    Person person("Harvey", 12);  
    cout << person->getName();  
}
```

Note that *person* is not a pointer.

- ❖ Evaluating rules of a smart pointer:

If the target is a pointer, `->` operator is evaluated as it normally is.

If it is an object with an overloaded `->` operator, the object is replaced by the output of the function

```
person->getName()  - - - - ->  m_ptrNameObject->getName();
```

The process continues until evaluation occurs normally (i.e. the lhs of `->` operator is a pointer).

operator new / operator delete

- ✧ You can have your own **new** and **delete** for a particular object

```
class Random {  
public:  
    Random(int data);  
    int getData();  
    void *operator new(size_t objectSize);  
    void operator delete(void *object);  
private:  
    int m_data;  
};  
void *Random::operator new(size_t objectSize) {  
    cout << "new\n";  
    return malloc(objectSize);  
}  
void Random::operator delete(void *object) {  
    cout << "delete\n";  
    free(object);  
}
```

compiler would determine suitable value for objectSize and invoke this function

Note: after calling

- ① **Random::operator new()**
- ② **Random::Random(int)**

- ✧ Usage:

```
void main() {  
    Random *ptr = new Random(20);  
    delete ptr;  
}
```

delete also does two things automatically²⁴⁻²⁹

operator new[] / operator delete[]

```
class Random {  
public:  
    Random();  
    int getData();  
    void *operator new[](size_t objectSize);  
    void operator delete[](void *object);  
private:  
    int m_data;  
};  
void *Random::operator new[](size_t objectSize) {  
    cout << "new[] objectSize=" << objectSize << "\n";  
    return malloc(objectSize);  
}  
void Random::operator delete[](void *object) {  
    cout << "delete[]\n";  
    free(object);  
}
```

✧ Usage:

```
void main() {  
    Random *ptr = new Random[5];  
    delete[] ptr;  
}
```

Note: after calling

- ① **Random::operator new[]()**
new would invoke 5 times the default ctor
- ② **Random::Random()**

delete also does two things automatically

operator new / operator delete

- ❖ Why should one override new, new[], delete, delete[]?
 - ★ One can allocate/deallocate memory from an internal memory pool instead of standard malloc/free
- ❖ Can you see why new[]/delete or new/delete[] would fail?
 - ★ For a delete[] operator, the internal mechanism should try to invoke destructors for all objects. If that block of memory was allocated with new.... Error occurs
 - ★ For a delete operator, the internal mechanism only invoke destructor once. If that block of memory was allocated with new[] ... Many objects will not be suitably destructed

Type Conversion

- ✧ Consider a simple string class

```
class String {  
public:  
    String();  
    String(char *inputData);  
    String(const String &src);  
    ~String();  
    const char *getString() const;  
private:  
    char *m_string;  
};
```

- ✧ This class allows conversions from ANSI C char arrays to the object of this class through the **type conversion constructor**

```
void main() {  
    String string1("hello");  
    String string2 = "bye"; // type conversion ctor then copy ctor  
}
```

- ✧ What about conversions in the other direction, from String class to ANSI C char array?

Type Conversion (cont'd)

- ❖ Type conversion operator (type coercion)

```
class String {  
public:  
    ...  
    String(const String &src);  
    operator const char *() const;  
    ...  
private:  
    char *m_string;  
};
```

const char*() was called in either
cout << strObj; or
cout << (const char *) strObj;
But different template libraries
have different behaviors.

- ❖ The definition

```
String::operator const char *() const {  
    return m_string;  
}
```

- * The function has **no return type**, despite the fact that it **does return a const char pointer!!!**

- ❖ Usage:

```
void main() {  
    String strObj("hello");  
    cout << strlen(strObj) << "\n";  
    cout << &strObj << " " << strObj << " " << (const char *) strObj << "\n";  
}
```

Output

5

00341E60 00341E60 Hello // vc98

00341E60 Hello Hello // vc 2008,10

Overload Unary +

- ❖ **Binary** syntax: object1 - object2

```
Complex Complex::operator-(Complex &secondNumber) const {  
    Complex tmp(m_real-secondNumber.m_real,  
                m_imaginary-secondNumber.m_imaginary);  
    return tmp;  
}
```

- ❖ **Unary** syntax: -object

```
Complex Complex::operator-() const {  
    return Complex(-m_real, -m_imaginary);  
}
```

Miscellaneous

❖ Can you overload every operator?

★ No.

★ There are some operator that cannot be overloaded

•
•*
•:
•?:

sizeof

❖ Can you create *new* operators?

★ No. For example, you cannot do this in C++: `y:=x;`

. * and ->* operators

❖ Pointer to member

```
class Car
{
public:
    int speed;
    int fuel;
};

int main()
{
    int Car::*ptr = &Car::speed;
    Car car;
    car.speed = 1;    // direct access
    cout << car.speed << endl;
```

Compare with

```
int *regular_ptr = &car.fuel;
```

❖ Dereference of a pointer to member

```
car.*ptr = 2;    // access via pointer to member
cout << car.speed << endl;
```

```
Car *ptrCar = &car;
ptrCar->*ptr = 3;    // access via pointer to member
cout << car.speed << endl;
```

```
ptr = &Car::fuel;
car.fuel = 4;
cout << car.*ptr << endl;
```

Output is

1
2
3
4
